Cloud service models are typically deployed and delivered through a process called cloud deployment. This involves a series of steps that enable users to access cloud resources and services.

Here are the steps involved in deploying and delivering cloud service models:

1. Provisioning: The cloud provider sets up the infrastructure and services needed to deliver the cloud service model. This involves setting up servers, storage, networking, and other resources required to run the service.
2. Configuration: The cloud provider configures the infrastructure and services to meet the specific needs of the user. This involves setting up security measures, customizing software settings, and configuring access controls.
3. Deployment: The user deploys their application, platform, or software on the cloud infrastructure. This can be done by uploading a file, using a command-line tool, or using a graphical user interface (GUI).
4. Monitoring: The cloud provider monitors the infrastructure and services to ensure they are running smoothly. This involves monitoring resource usage, identifying bottlenecks, and resolving issues.
5. Scaling: If the user needs more resources to support their application, the cloud provider can scale up or down the infrastructure to meet their needs. This can be done automatically or manually, depending on the provider's capabilities.
6. Delivery: Once the service is deployed and running, the user can access it over the internet using a web browser or other client application. This can be done from anywhere, as long as there is an internet connection.

Here is a diagram that illustrates the deployment and delivery of cloud service models:
